Patent Summary

This patent details the design and control for wheel-legged robots navigating high obstacles. The methods explained include using a balance controller and rolling controller to use thigh joint torque and calf joint torque for efficiency. Legged robots are able to navigate high terrain with obstacles, so optimizing performance is viable with nonlinear programming.

Patent Critique

This relates to our HUNCH project as we also need to design a robot that can navigate and travel across high terrain, aka the lunar surface. Our robot will have wheels, so it's imperative that it travels safely and reaches the planned destination without any hurdles. Even though this patent gives us information on wheels in rugged terrain, it doesn't directly deal with the lunar surface.
