Product Summary:

The Astrolab CLV-1 is a crewed lunar rover chosen by NASA to support astronaut missions and carry cargo at the Moon's south pole. It can be driven by humans or operated remotely during the night. It can carry 2 suited astronauts and heavy supplies as well, and it can conduct select surface operations remotely.

Product Critique:

As opposed to carrying external payloads, this rover focuses on carrying the astronauts and their supplies. Our robot must carry other cargo pods, and adapt to their sizes, while also sufficiently navigating across the lunar surface. However, the rest of the rover aligns with our robot: autonomous navigation across the lunar surface with sufficient space to carry certain supplies.
