Source:

Lando, NASA: LINK

Product Summary:

The Lightweight Surface Manipulation System AutoNomy was designed to pick up and move payloads around the lunar surface. The previous LSMS had low level scripted commands, so NASA engineers designed this to be able to detect titled landers, identify and manipulate objects. Overall, this robot was designed to be interchangeable to different lunar task and work more autonomously compared to previous models.

Product Critique:

This robot still depends on human supervision as it is designed for supervised autonomy rather than complete independence. It also mainly focuses on payload manipulation and not really transportation: it can unload and place payloads, but doesn't solve the problem of moving the cargo long distances across the lunar terrain.
