Product Summary:

The Lunar Surface Manipulation System (LSMS) is a hybrid device with the strength of a crane and precise robotic manipulation. It is engineered for various tasks on the surface of the Moon (or other planets), such as unloading langers, moving payloads, and installing different types of infrastructure. It's very versatile for lunar exploration, including important steps such as offloading a lander, precisely placing itself around the cargo, and swapping between tools for efficiency.

Product Critique:

We can take inspiration from this product for a part of our robot. We need to design a robotic arm that will pick up various sizes of cargo and place it inside our robot to clean. This design employs various robotic joints and heightened crane capacity. It acts as a crane hybrid that can be mounted either near a lander or on top of a mobile base.
