## Product Summary:

*The Lunar Outpost Pegasus is a next-generation crewed LTV selected by NASA to transport Artemis astronauts across the lunar surface to the Moon's South Pole. It provides very critical surface mobility for operational duties, works autonomously with teleoperation, which provides flexibility on multiple missions.*

## Product Critique:

*The Pegasus LTV can help us design autonomous movement across the lunar surface, in all aspects. Our robot must transport cargo from the payload lander to the habitat autonomously, and this LTV covers almost all of those aspects. It details movement across lunar terrain, autonomous systems, and surface mobility. However, it primarily transports astronauts, while our robot is for transporting cargo.*
